# REGRESSION ANALYSIS

Walpole, R. E., Myers, R. H., Myers, S. L., & Ye, K. (2012). Probability and Statistics for engineering and sciences. Pearson Education, 430-435.

**Finding** the best relationship between Y and x: not deterministic, random error

**Quantifying the strength** of that relationship. Random error with  $E(\text{error})=0$  and homoscedasticity. Least Squared Estimation (LSE)

**Predicting** of the response value y given values of the regressor x.

harus  
dipenuhi

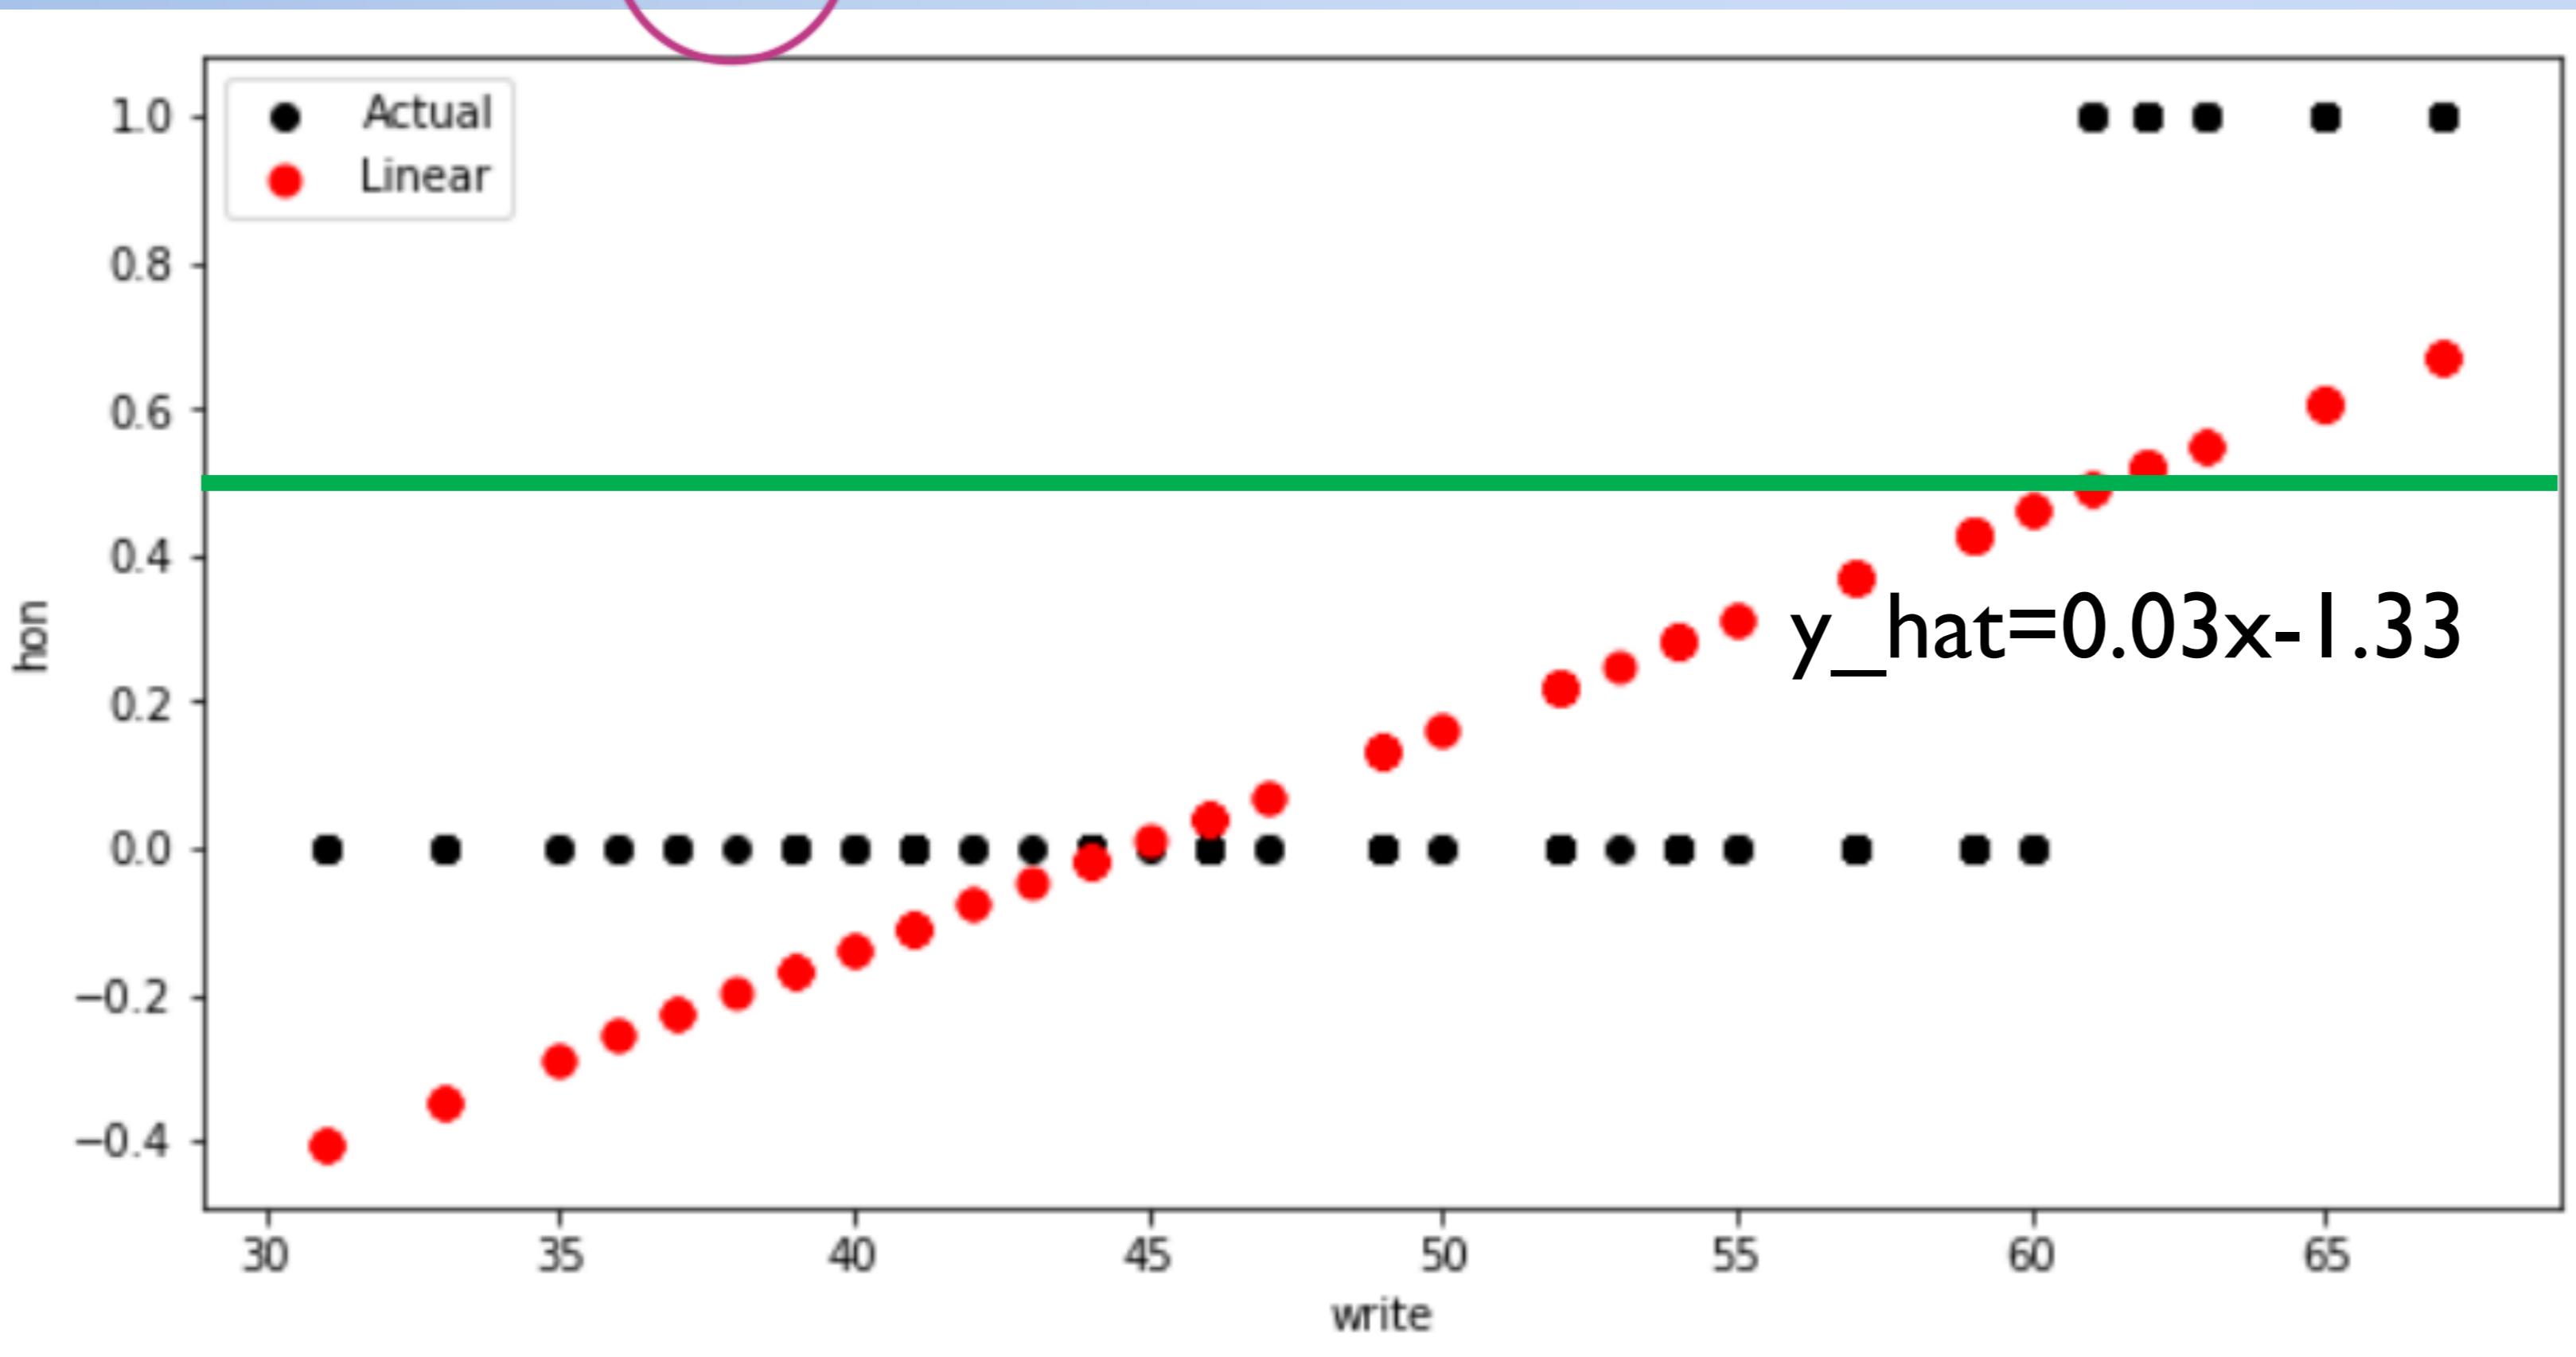

# CLASSIFICATION USING LINEAR REGRESSION

## LINEAR REGRESSION + THRESHOLD

Example: Dataset has 200 observations (5 attributes), and the target attribute is **hon**, indicating if a student is in an honors class or not.

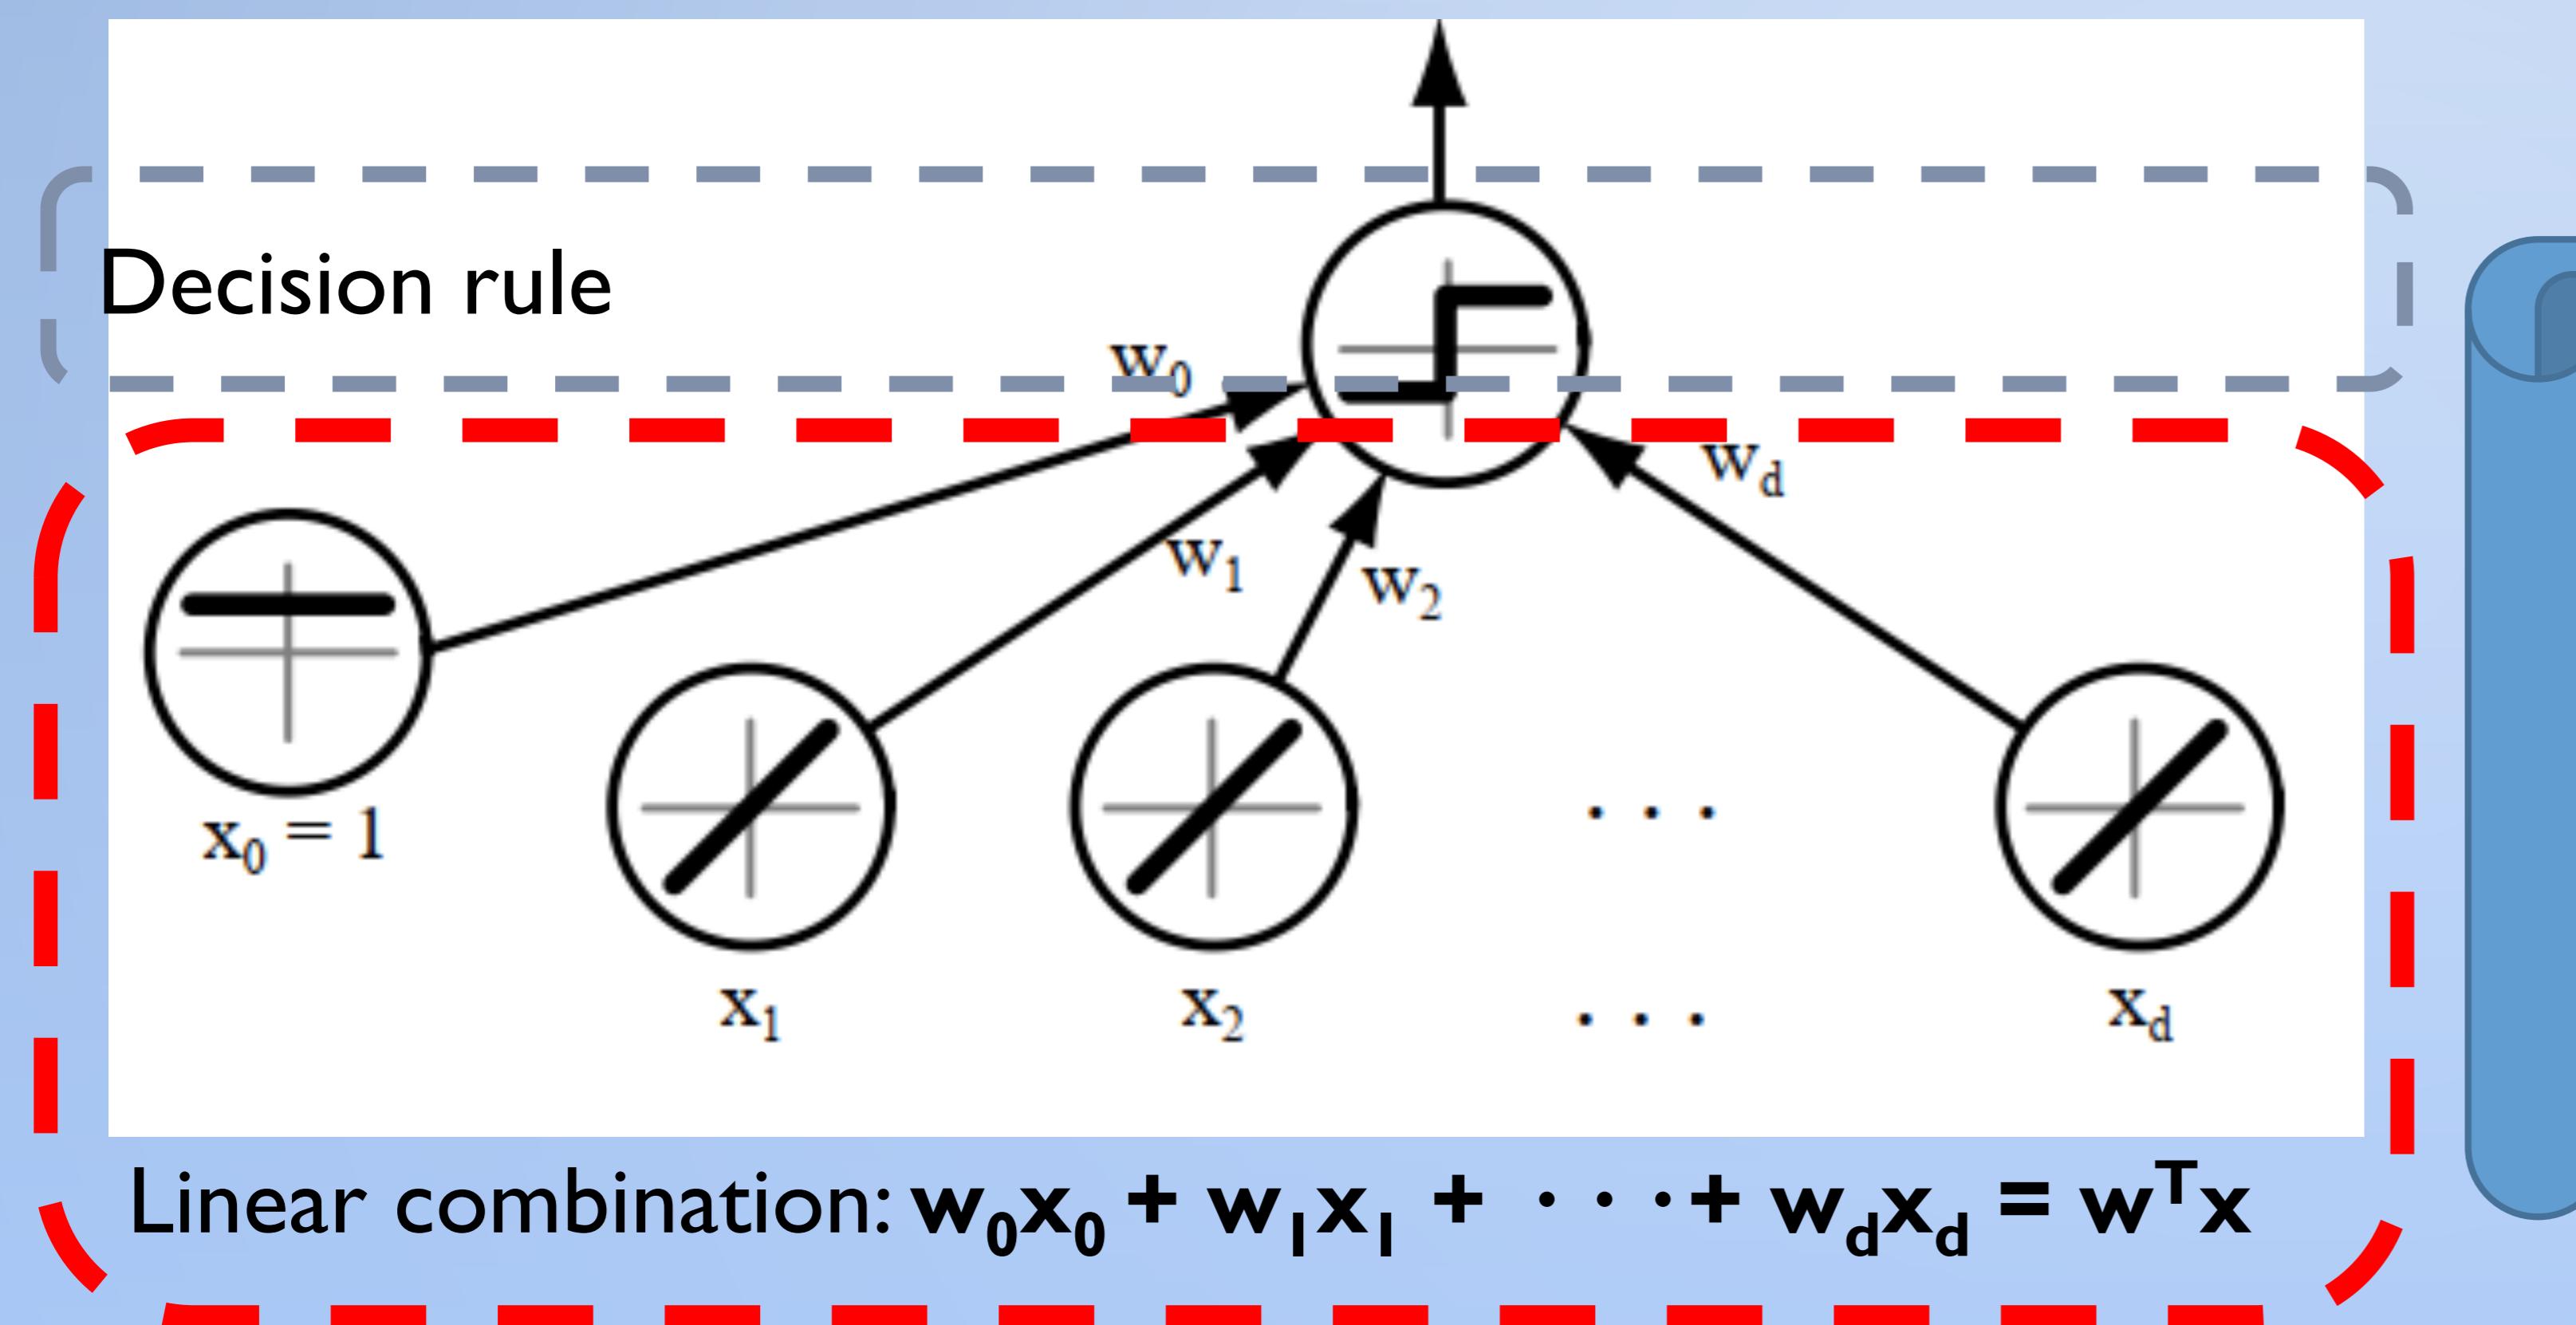

We are able to predict the value along the Y-axis. If Y is greater than 0.5 (above the green line), predict that the student is in honor class otherwise not in honor class.

Linear Model or  
Linear Discriminant Function  
or Linear Classifier

# LINEAR DISCRIMINANT FUNCTION

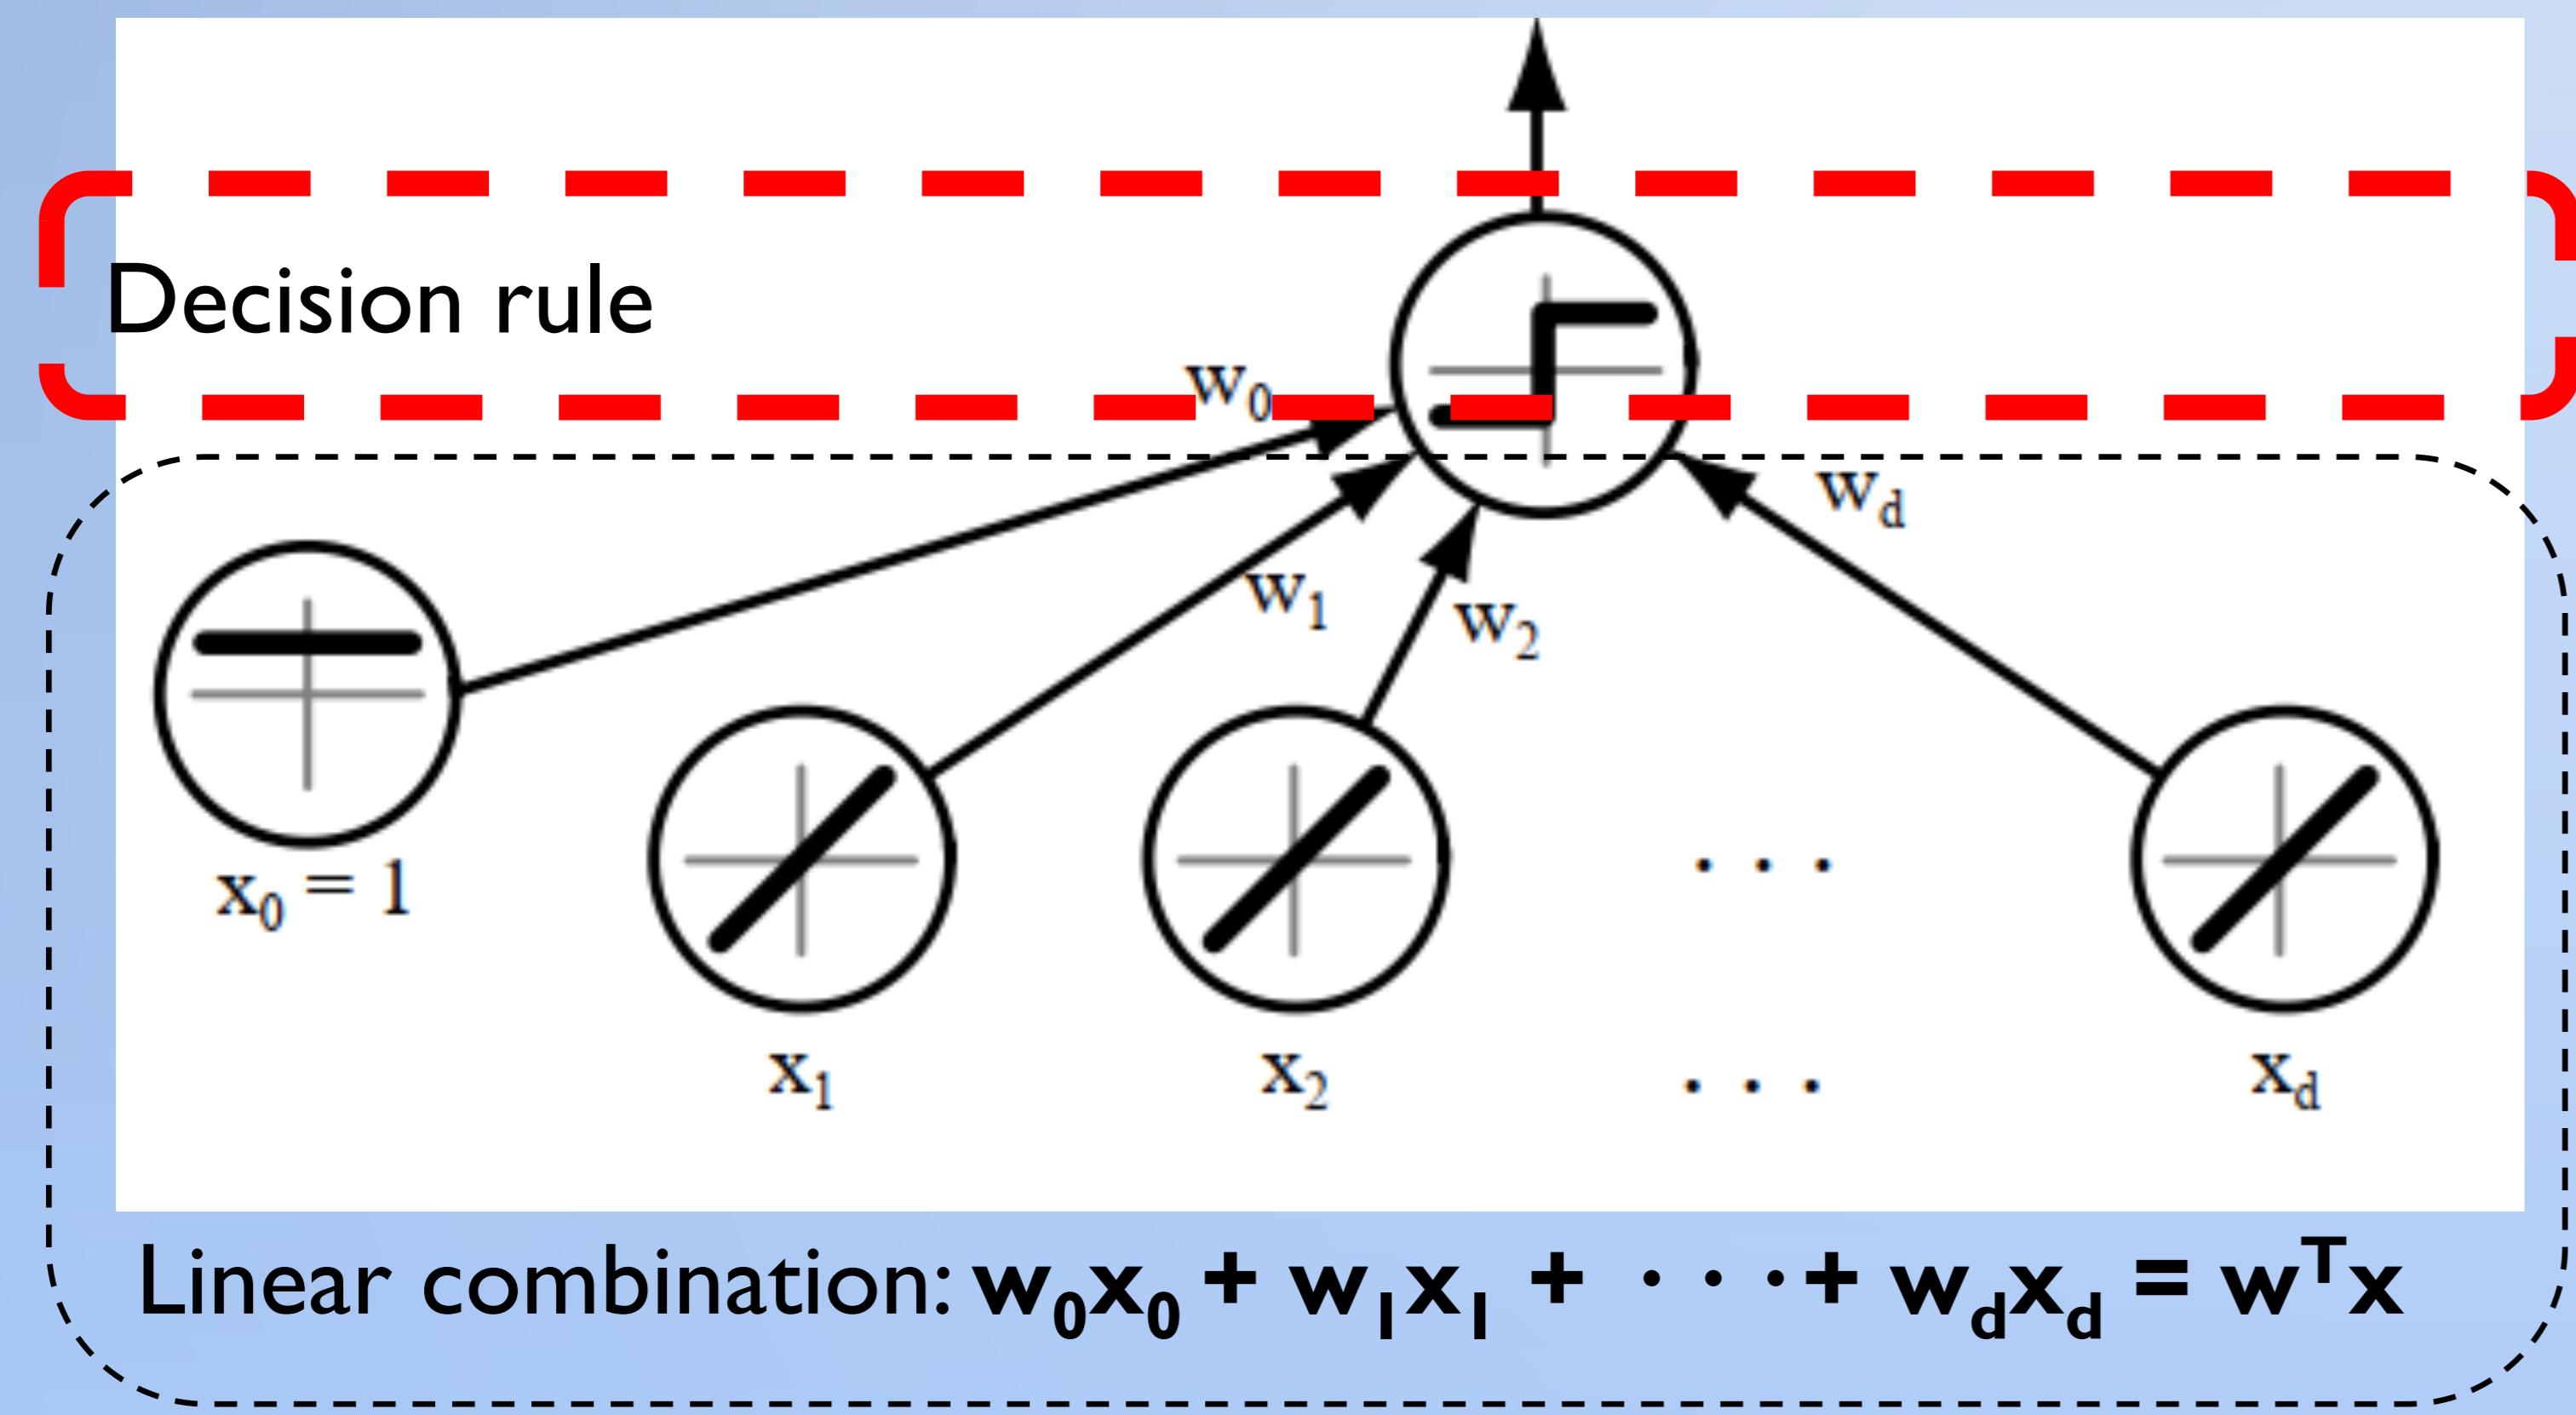

## LINEAR COMBINATION + DECISION RULE

Discriminant function:  
a linear combination of the  
components of  $x$

$$g(x) = w_0x_0 + w_1x_1 + \dots + w_dx_d = w^T x$$

# HYPERPLANE DECISION SURFACE

**Discriminant function:**  

$$g(x) = w^T x$$

**Decision rule:**  
 Decide  $\omega_1$  if  $g(x) > 0$  and  $\omega_2$  if  $g(x) < 0$   
 $g(x) = 0$ : decision surface  
 $\omega_1$  and  $\omega_2$  are target classes

# HYPERPLANE DECISION SURFACE

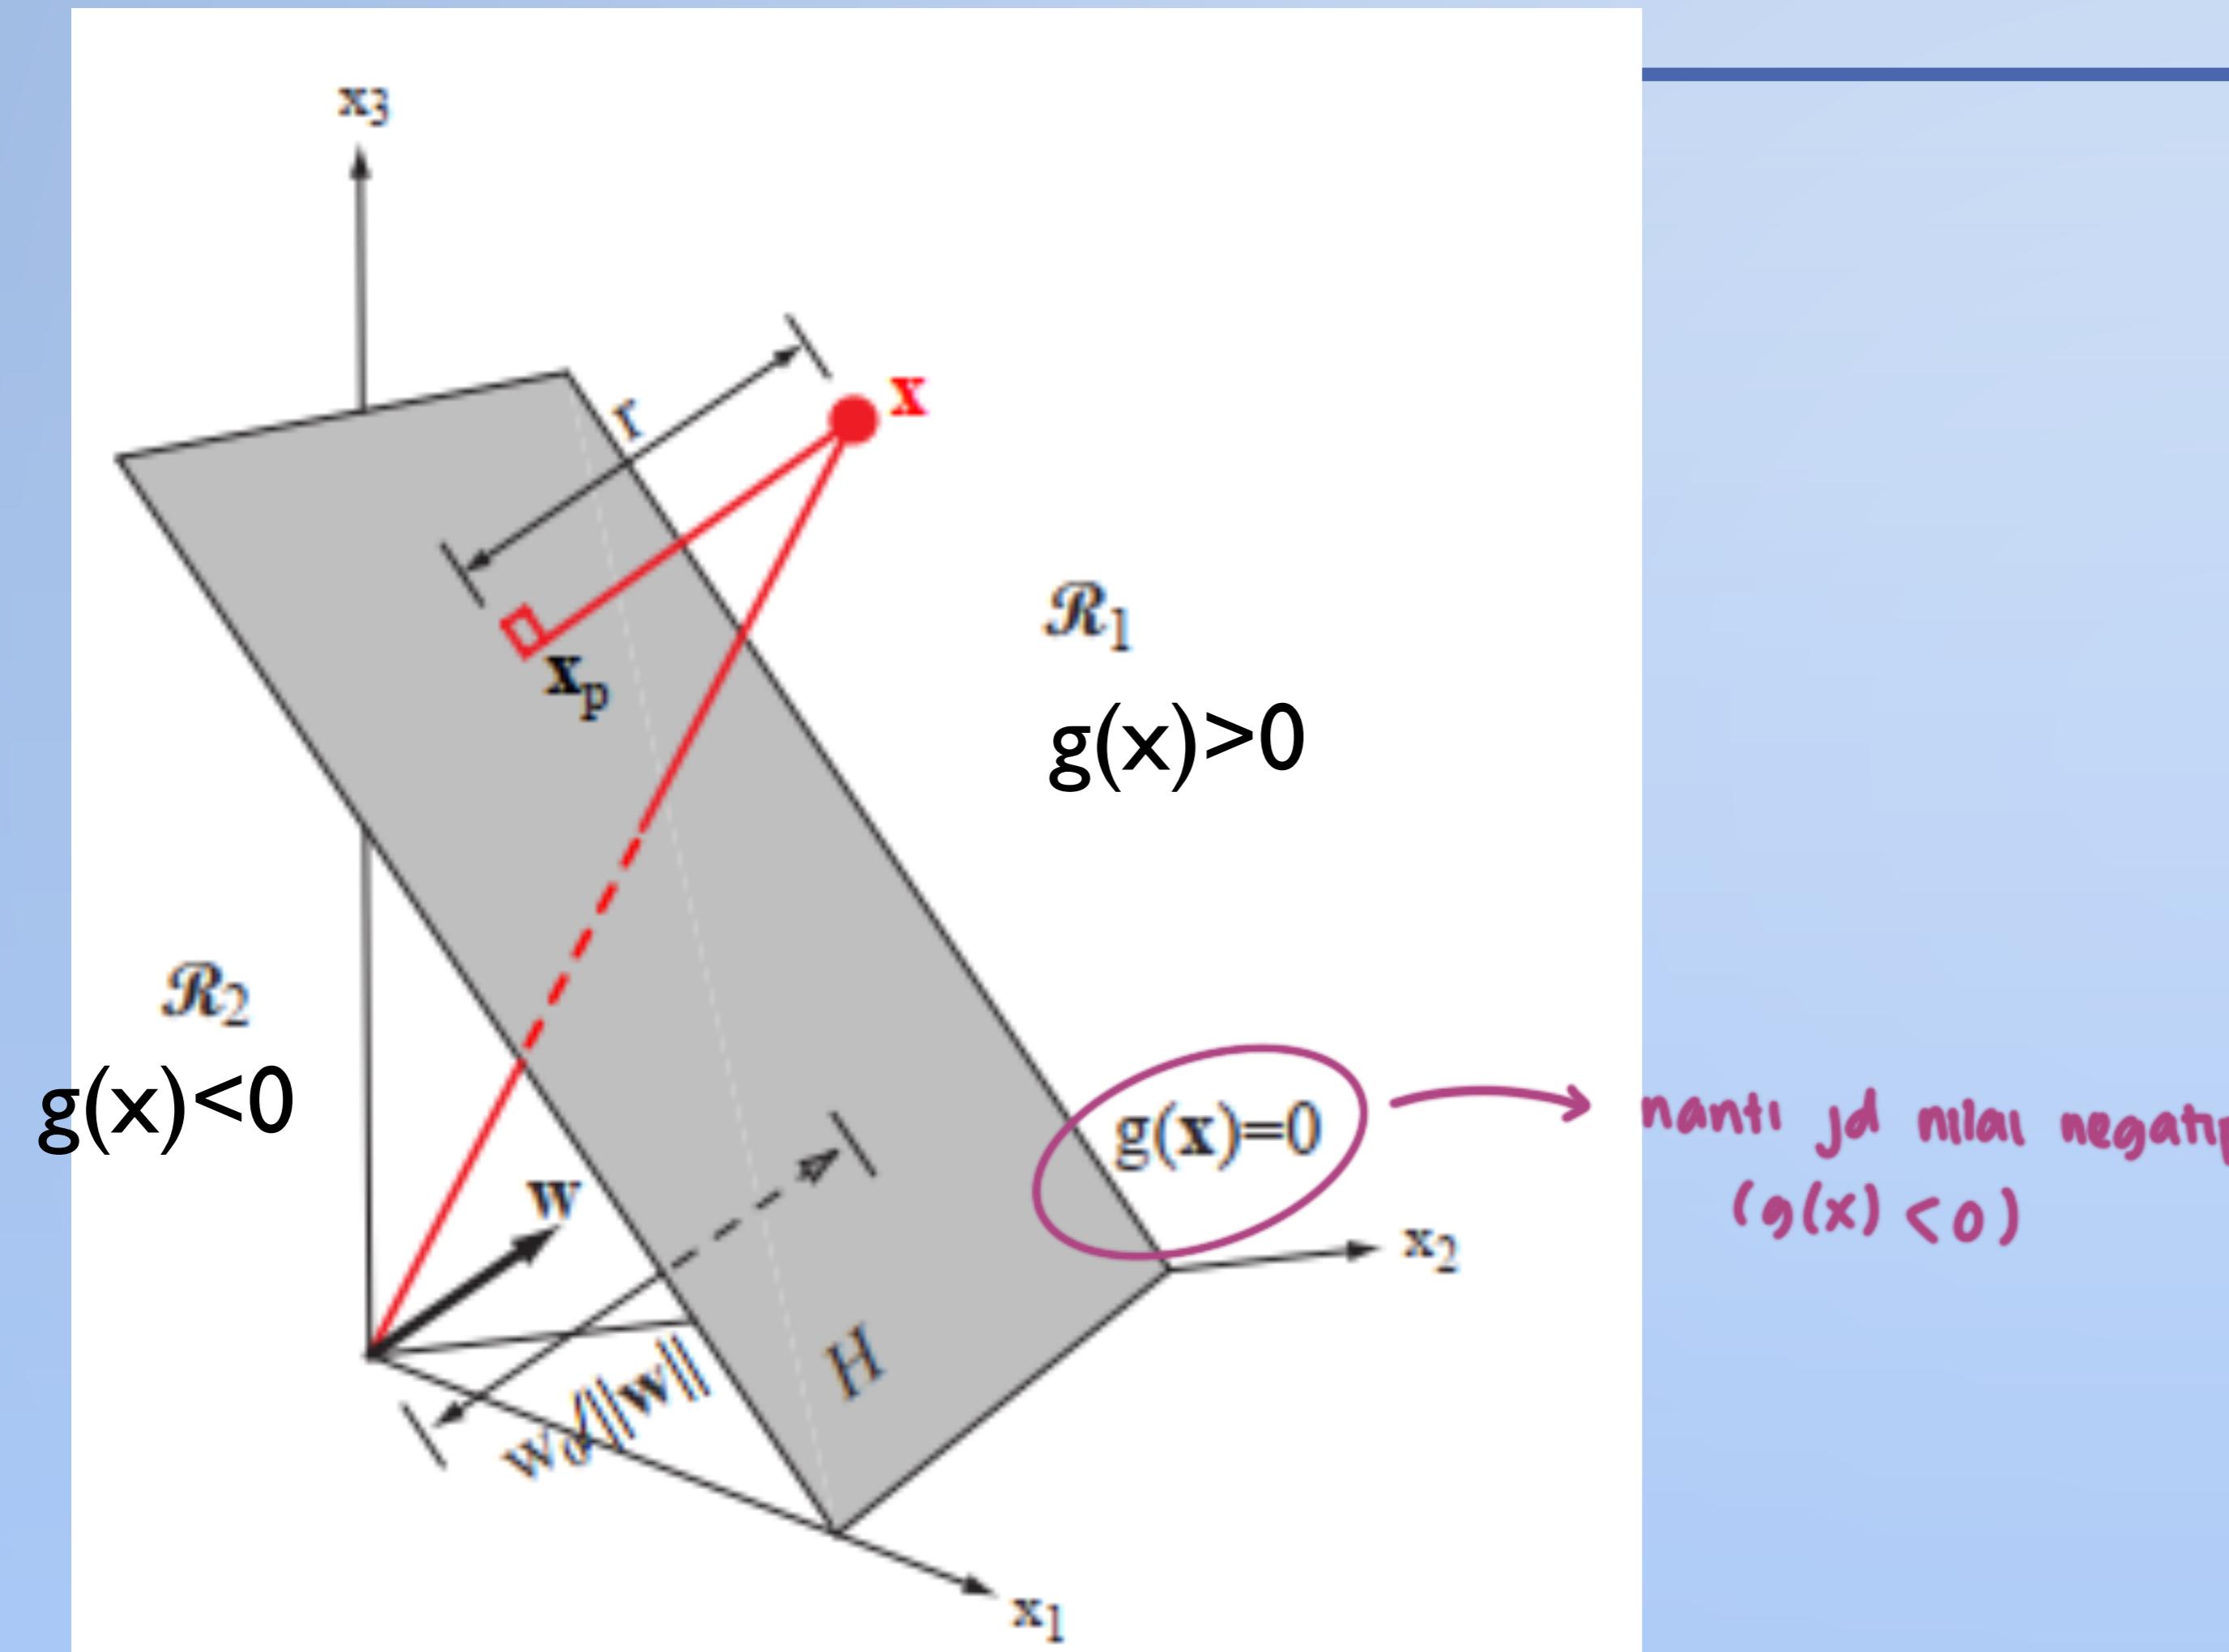

Figure 5.2: The linear decision boundary  $H$ , where  $g(\mathbf{x}) = \mathbf{w}^T \mathbf{x} + w_0 = 0$ , separates the feature space into two half-spaces  $\mathcal{R}_1$  (where  $g(\mathbf{x}) > 0$ ) and  $\mathcal{R}_2$  (where  $g(\mathbf{x}) < 0$ ).

**Discriminant function:**  

$$g(\mathbf{x}) = \mathbf{w}^T \mathbf{x}$$

**Decision rule:**  
 Decide  $\omega_1$  if  $g(\mathbf{x}) > 0$  and  $\omega_2$  if  $g(\mathbf{x}) < 0$   
 $g(\mathbf{x}) = 0$ : decision surface  
 $\omega_1$  and  $\omega_2$  are target classes

# LOGISTIC REGRESSION

$$\hat{y} = \log\left(\frac{p}{1-p}\right) = \mathbf{b}^T \mathbf{x} = b_0 \cdot 1 + b_1 x_1 + \cdots + b_d x_d$$

Walpole et al. (2012):  
 Odds of success =  $p/(1-p)$   
 Logistic regression estimates the probability of classes:

$$p = P(y = 1 | \mathbf{x}, \mathbf{b}) = \frac{1}{1 + e^{-\mathbf{b}^T \mathbf{x}}}$$

Coefficients in logistic regression are in terms of the log odds, that is, the coefficient 0.08 implies that a one unit change in "write" results in a 0.08 unit change in the log of the odds.

<https://stats.idre.ucla.edu/stata/faq/how-do-i-interpret-odds-ratios-in-logistic-regression/>

# EXERCISE

linear regression

$$\hat{y} = 0.07x - 4.85$$

$$= 0.07(65) - 4.85$$

$$= -0.3$$

$$\therefore \text{kelas } 0$$

logistic regression

$$\hat{y} = 0.03x - 1.35$$

$$= 0.03(65) - 1.35$$

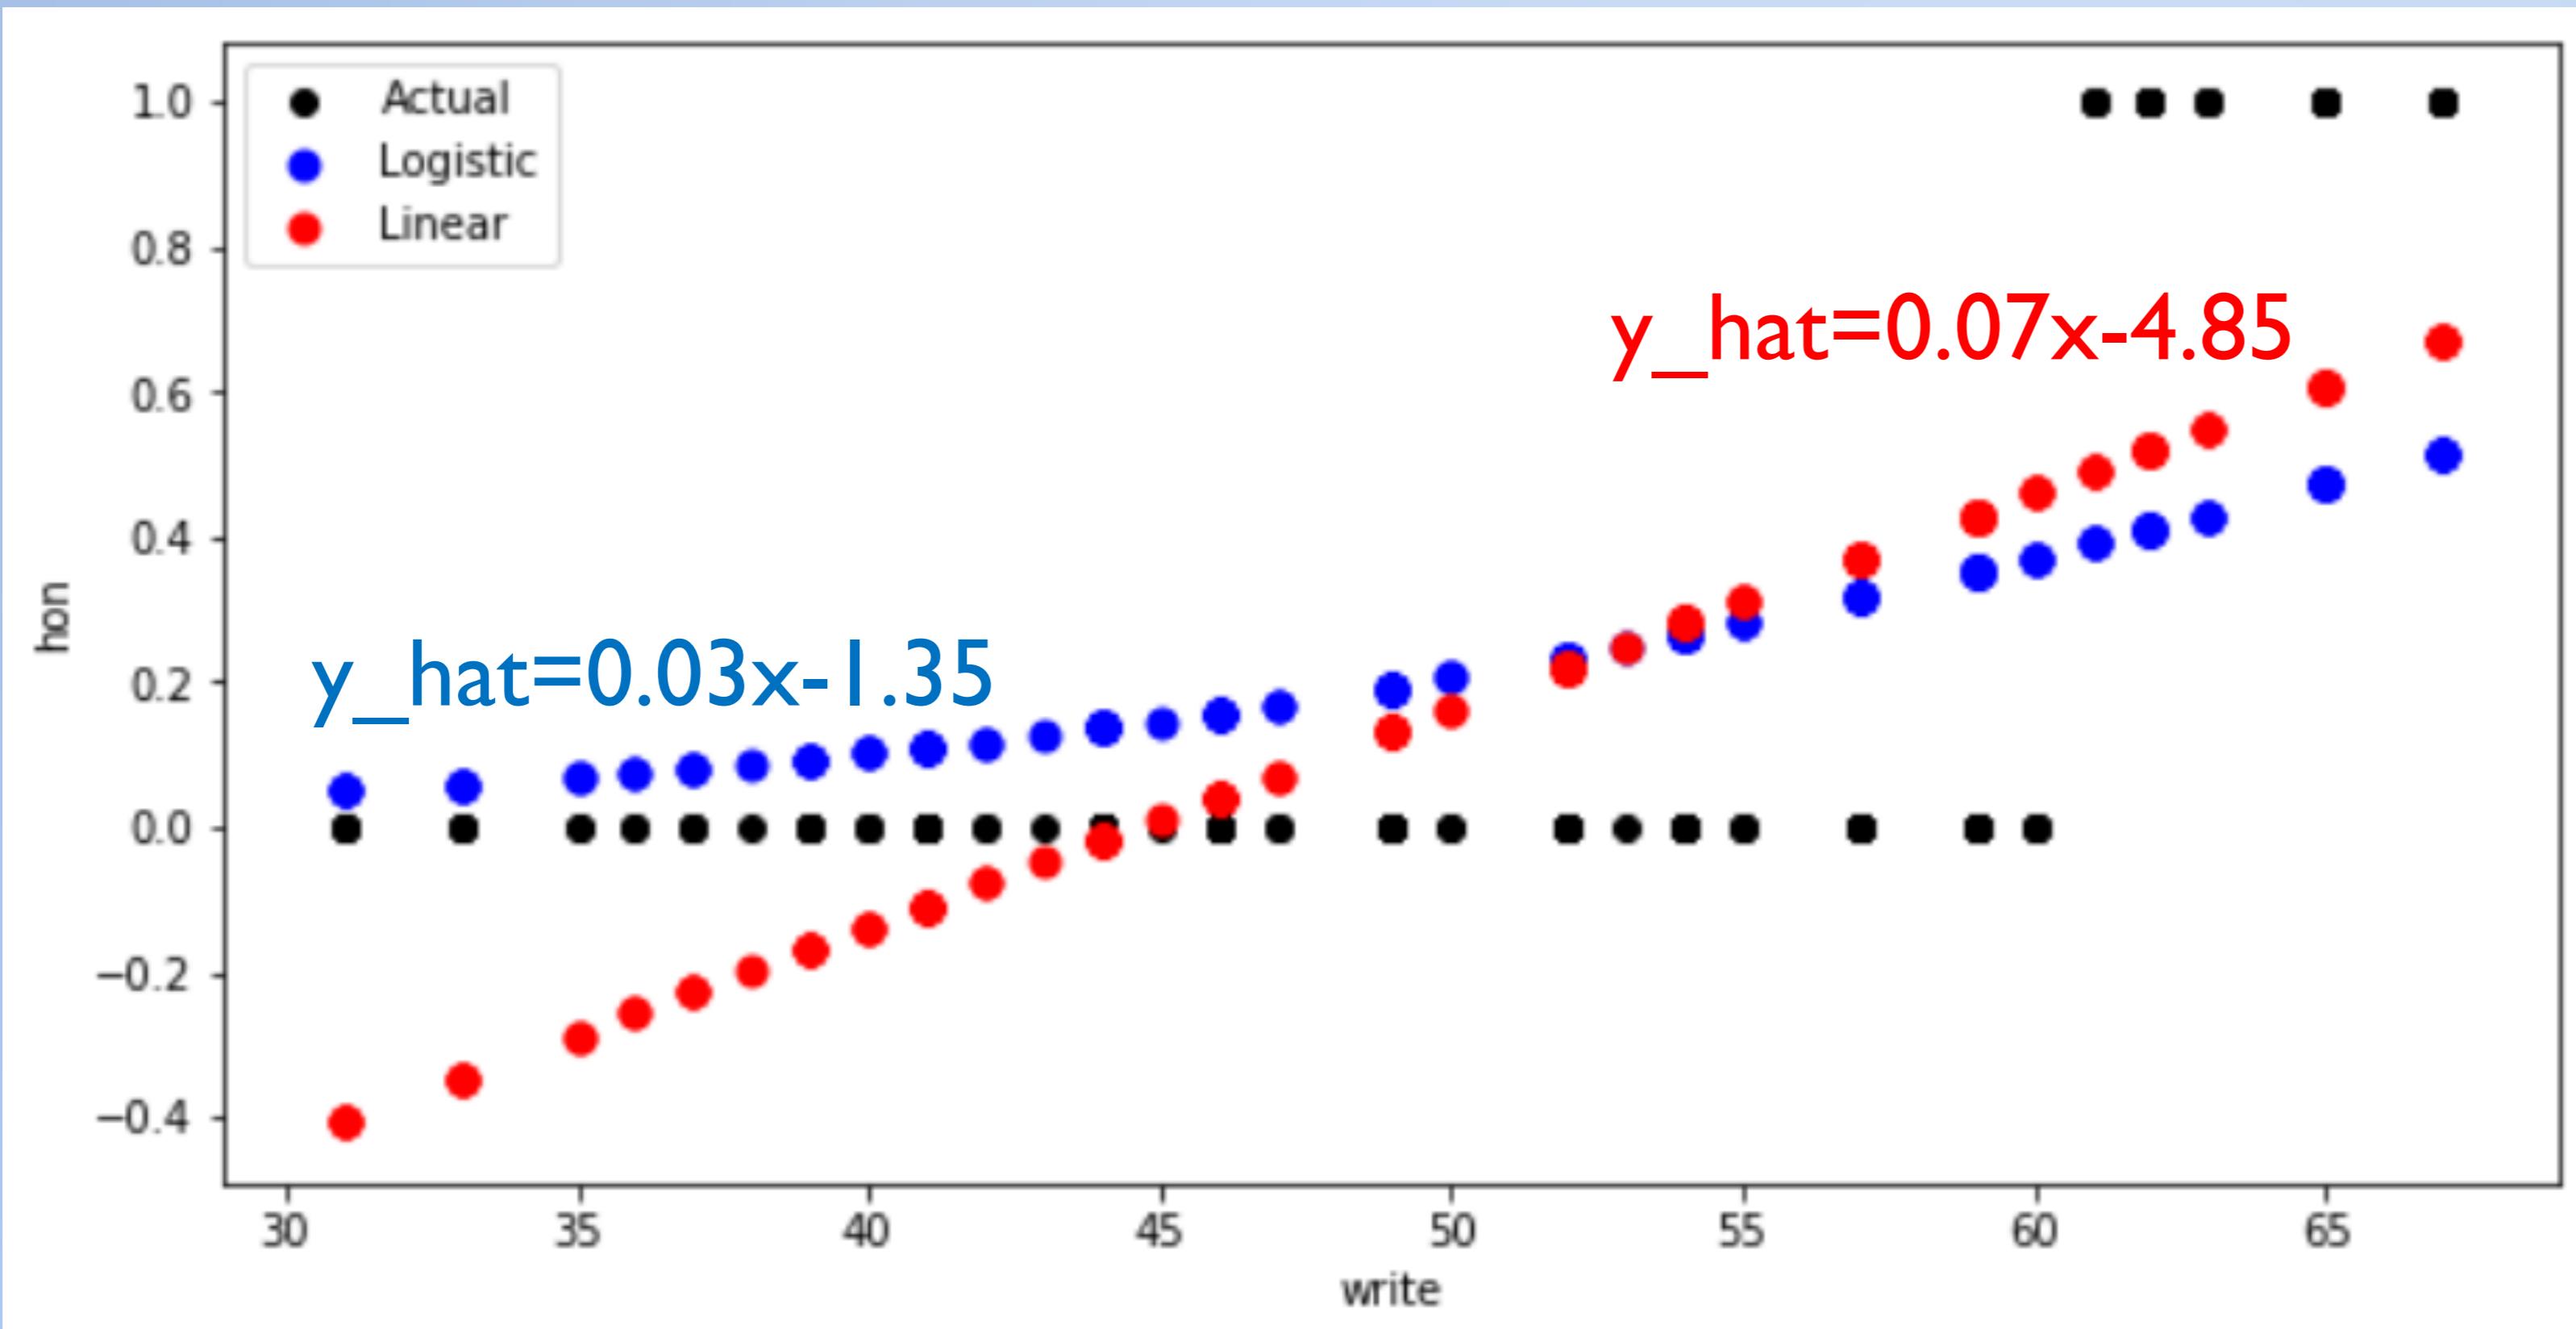

$$= 0.6$$

$$p = p(\text{kelas } 1 | x)$$

$$= \frac{1}{1 + e^{-0.6}} = \frac{1}{1 + e^{-0.6}} = 0.65$$

$\therefore \text{kelas } 1$

Given these linear regression and logistic regression models, determine whether a student that has write score 65 is in honors class.

## linear regression

$$\hat{y} = 0,07x - 4,85 \\ x: 65 \rightarrow \hat{y} = (0,07 \cdot 65) - 4,85 = 0,3 \rightarrow \hat{y} = -0,3 < 0,5 \rightarrow \text{kelas } 0$$

## logistic regression

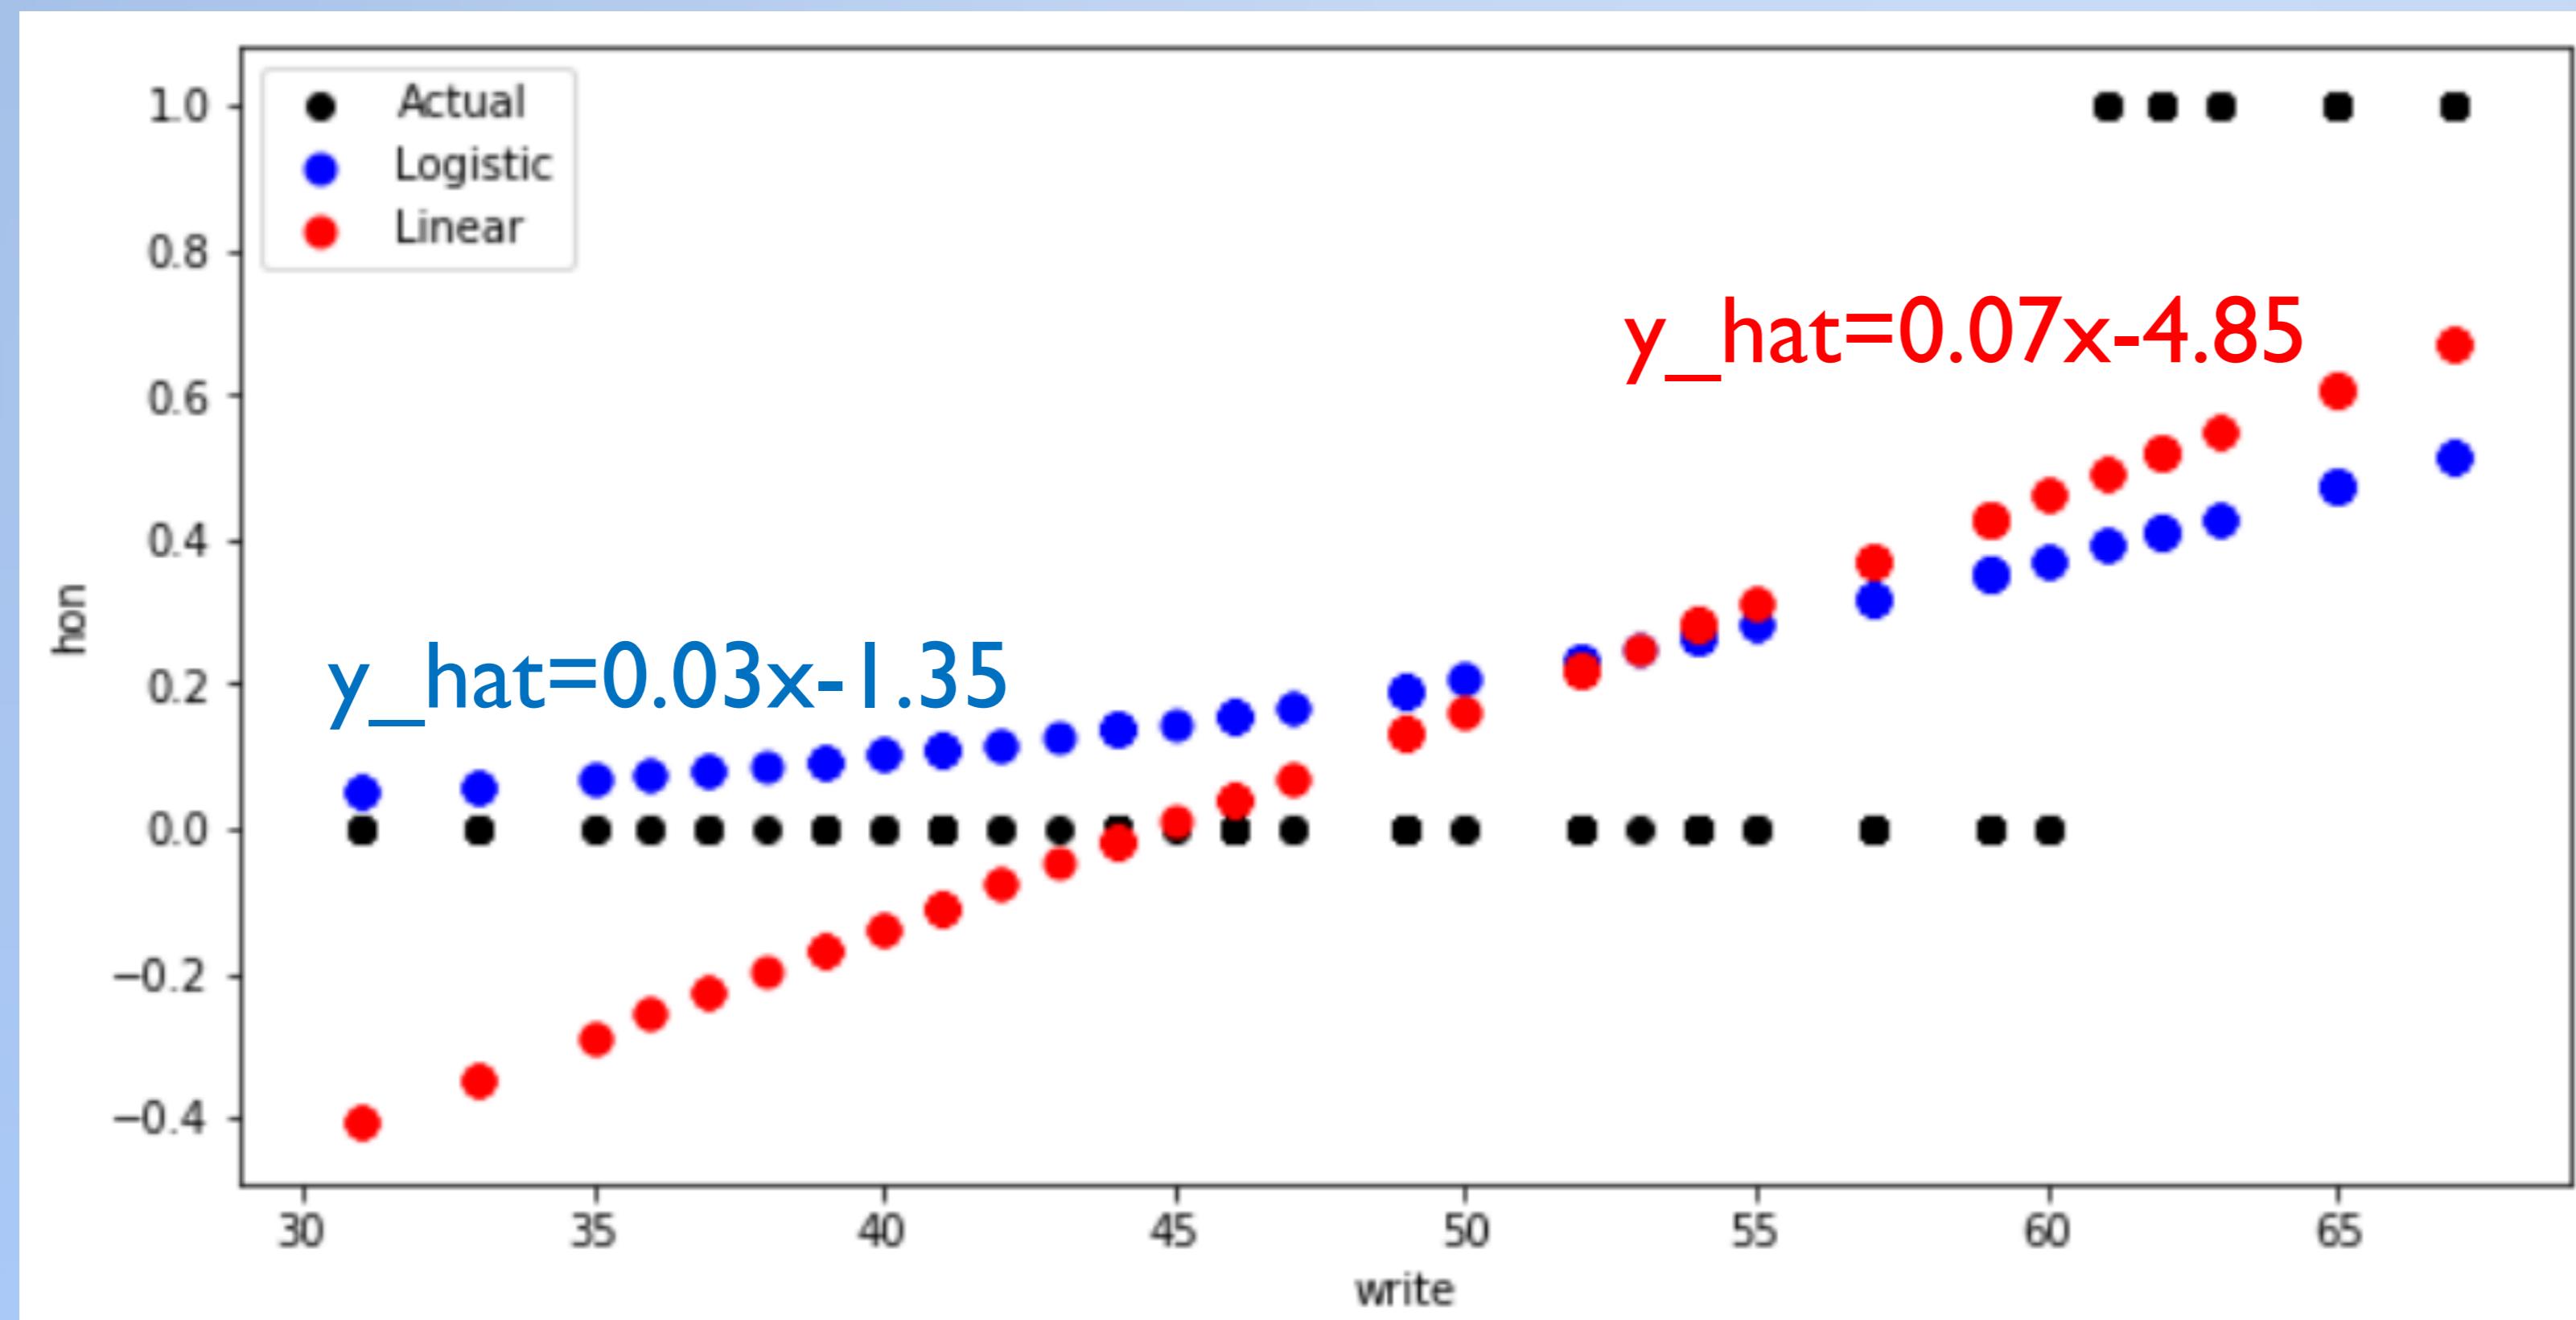

$$\hat{y} = 0,03x - 1,35 \\ x: 65 \rightarrow \hat{y} = (0,03 \cdot 65) - 1,35 = 0,6 \rightarrow p = p(\text{kelas } 1 | x) \\ = \frac{1}{1 + e^{-0,6}} \\ = 0,645 > 0,5 \rightarrow \text{kelas } 1$$

## EXERCISE: SOLUTION

Given these linear regression and logistic regression models, determine whether a student that has write score 65 is in honors class.

Linear regression:

$$y_{\text{hat}}(x)=0.07x-4.85$$

$$y_{\text{hat}}(65)=0.07*65-4.85= -0.3$$

Class: 0 ( $y_{\text{hat}}= -0.3 < 0.5$ )

Logistic regression:

$$y_{\text{hat}}(x)=0.03x-1.35$$

$$y_{\text{hat}}(65)=0.03*65-1.35= 0.6$$

$$p=1/(1+e^{-0.6})=0.65$$

Class: 1 ( $y_{\text{hat}}=0.65 > 0.5$ )

# 16 MAXIMUM LIKELIHOOD ESTIMATOR FOR LOGISTIC REGRESSION

ESTIMATOR THAT RESULTS IN A MAXIMUM VALUE FOR ITS JOINT PROBABILITY OR MAXIMIZES THE LIKELIHOOD OF THE SAMPLE

Formal definition

(Elkan, 2014):

local search

Given the training set  $\{<\mathbf{x}_1, \mathbf{y}_1>..<\mathbf{x}_n, \mathbf{y}_n>\}$ , learn logistic regression classifier by maximizing the log joint conditional likelihood, that is the sum of log conditional likelihood (LCL) for each training example.  $x_{ij}$  is the value of the jth feature of the ith training example.

$$LCL = \sum_{i=1}^n \log L(\theta; \mathbf{y}_i | \mathbf{x}_i) = \sum_{i=1}^n \log p_i + \sum_{i=1}^n \log(1 - p_i)$$
$$\rightarrow \frac{\partial LCL}{\partial b_j} = \sum_i (y_i - p_i) x_{ij}$$

peluang estimasi  
nilai sebenarnya  
pd label

Stochastic gradient ascent is optimization method that changes the coefficient values (as random approximation to true derivative) to increase the log likelihood based on a randomly chosen example at a time.

Stochastic gradient update of  $b_j$  is:

$\eta$  : learning rate

$$b_j = b_j + \eta(y_i - p_i)x_{ij}$$

<https://cseweb.ucsd.edu/~elkan/250B/logreg.pdf>

learning rate ( $0 < \eta < 1$ )  
makin kecil makin bagus (?)
